

How does

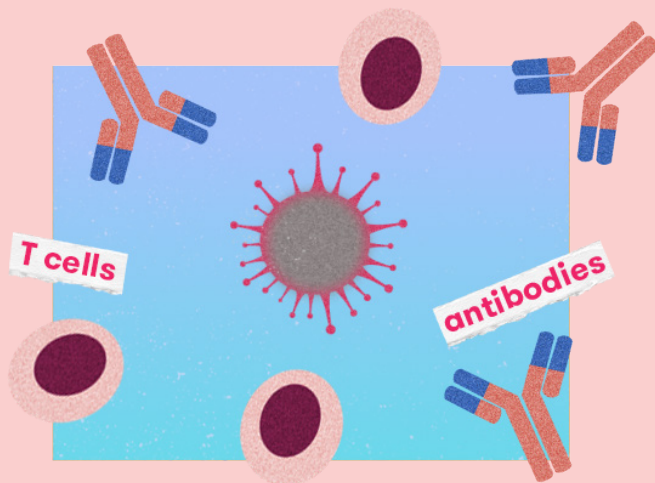

the COVID-19 vaccine work?

Scientists made the vaccine by using part of the unique genetic code of the coronavirus.

This code instructs your cells to make a small, harmless piece of the virus called the spike protein.

Our bodies respond by making antibodies and activating T cells to destroy the spike protein.

This teaches your immune system to recognize and destroy the virus, and will have the antibodies and memory T cells ready if you ever become infected.

Vaccines save lives and help keep us healthy.
